few concerns are listed

- Wi-Fi connectivity should be seamless to the user, what I mean to say is the phone should automatically connect to any available hotspot and handoff from one hotspot to the next without the user having to manually re-connect in every different location. Only a one time registration should be done on the phone giving the customer the best experience.
- Security of data transmitted over the hotspot is very important and customers may fall victim to phishing/man in the middle based attacks. The provider of the network must ensure that such attacks do not take place.
- The network must have good backed connectivity based on fiber/etc. Ad- Hoc solutions such as wifi range boosters must not be used.
- The wi-fi network must be able to adequately serve each and every customer and a certain quality of service must be met for each and every customer.
- Net neutrality must be upheld and some protocols/websites must not be discriminated against such as torrents,youtube,etc
Regards
